SY-03 Map of existing books and the gap

The Tripartite Framework of Sex Differences

Developing a foundational architecture for how men and women can optimally live, work, and build societies together necessitates navigating one of the most intellectually contested terrains in the behavioural and biological sciences. The existing literature on sex and gender is overwhelmingly bifurcated into biological determinism on one side and social constructivism on the other. To systematically map this literature and identify the unoccupied theoretical position, it is mandatory to establish a rigorous ontological framework that separates human sex differences into three distinct but perpetually interacting layers.

The first layer is physiology, which is fundamentally measurable and bimodal. This layer encompasses the genetic, endocrine, and gross anatomical realities of the human species, including chromosomal configurations, gonadal development, gamete size asymmetry, and baseline exposure to organizational and activational hormones such as testosterone, estrogen, oxytocin, and vasopressin. These variables are highly dimorphic and form the biological substrate upon which all subsequent development occurs.

The second layer encompasses behaviour and cognition. Unlike physiological sex, behavioural sex differences are almost exclusively statistical phenomena, represented by overlapping normal distributions rather than binary categories. This layer includes psychological traits, cognitive abilities, mating preferences, and aggressive tendencies. The statistical nature of this layer is precisely what allows for immense individual variation within deeply patterned group averages.

The third layer is culture. This represents the variable sociological, historical, and institutional norms that either amplify, suppress, or redirect the physiological and behavioural baselines. Culture is highly plastic, but it is not infinitely malleable; it operates within the constraints established by the first two layers. A rigorous analysis of human interaction must account for all three layers without collapsing them into one another.

Averages Versus Individuals: The Methodological Divide

A pervasive methodological error in the literature on sex differences—and a primary driver of the academic controversies surrounding the topic—is the conflation of group averages with individual prediction. Evaluating the existing corpus of literature requires understanding how the magnitude of sex differences is statistically quantified, most commonly using Cohen's d, which represents the standardized mean difference between two groups.

In a monumental meta-synthesis published in the *American Psychologist* by Zell, Krizan, and Teeter (2015), which aggregated 106 meta-analyses encompassing over 12 million participants, the average absolute sex difference across all psychological domains was found to be $d = 0.21$ [1]. A d of 0.21 is statistically defined as "small" and corresponds to an 85% overlap between the male and female distributions[1]. The synthesis revealed that 85.5% of all

psychological sex differences are either small or negligible[3]. For highly specific traits, however, the differences widen. For instance, a meta-analysis on 3D mental rotation by Voyer et al. (1995) demonstrated a robust, widely replicated male advantage with an effect size of $d \approx 0.60$, which remains one of the largest cognitive sex differences in the psychological literature[5]. However, relying strictly on univariate (single-trait) averages profoundly obscures the complexity of the human organism. Del Giudice, Booth, and Irwing (2012), publishing in *PLoS ONE*, utilized a multidimensional effect size metric, the Mahalanobis distance (D), to evaluate personality differences across the Big Five traits simultaneously. They demonstrated that while individual traits show high overlap, when multiple interacting traits are calculated jointly, the global sex difference reaches $D = 2.71$ [2]. A Mahalanobis distance of 2.71 indicates an overlap of only about 10% between the sexes globally[7]. Therefore, while any single individual may defy the average on a specific, isolated trait, the aggregate multivariate profile of individuals remains highly sexually differentiated. Distinguishing what is known about univariate averages from what can be said about multivariate individuals is the essential lens through which the following literature must be evaluated.

Survey of Existing Book-Length Treatments

The existing literature attempting to decode sex differences and human interaction can be categorised into distinct theoretical camps. The following analysis maps these books, evaluating their central thesis, their primary evidence base, their primary readership demographics, their critical reception, and their limitations regarding the pragmatic design of human institutions and relationships.

Overview of the Literature Landscape

Author & Book	Primary Thesis	Core Evidence Base	Readership & Reception	What it Fails to Do (The Gap)
Ridley (*The Red Queen*), **Geary** (*Male, Female*), **Fisher** (*Anatomy of Love*)	Sexual selection drives dimorphic mating strategies and social architectures.	Evolutionary biology, primatology, cross-cultural surveys.	Academics, science enthusiasts. Highly influential but accused of determinism.	Provides ultimate evolutionary explanations but no proximate frameworks for modern institutional or relational design.

Benenson (*Warriors and Worriers*), **Baumeister** (*Is There Anything Good About Men?*)	Men evolved for lethal group conflict/utility; women for infant protection and relational survival.	Developmental psychology, historical demographics.	Evolutionary psychologists, sociologists. Praised for identifying dynamics, heavily criticized for group-selection theories.	Remains purely descriptive of macro-sociological clashes without proposing integration mechanisms for daily life.
Pinker (*The Blank Slate*), **Eliot** (*Pink Brain, Blue Brain*), **Rippon** (*The Gendered Brain*), **Saini** (*The Patriarchs*)	Pinker attacks constructivism; Eliot, Rippon, and Saini argue sex differences are socialized artifacts or historical accidents.	Cognitive science, sociology, structural MRI meta-analyses.	Progressive sociologists, feminists. Celebrated in media but fiercely contested by evolutionary biologists.	By insisting differences are illusory or purely cultural, they provide no tools for managing the statistically real multivariate differences that do exist.
Sapolsky (*Behave*), **Fine** (*Testosterone Rex*), **Hooven** (*T: The Story of Testosterone*)	Biology and environment co-create reality; debates center on testosterone as an active driver vs. a cultural myth.	Endocrinology, neurobiology, placebo-controlled behavioural studies.	Broad intellectual public. Sapolsky is universally acclaimed; Fine and Hooven represent polarized ideological camps.	Trapped at the molecular/neurochemical level. Fails to scale endocrine data up into holistic sociological or structural models.
Hrdy (*Mothers and Others*, *Father Time*)	Humans are cooperative breeders; men possess a latent,	Primatology, neuroendocrinology, developmental psychology.	Biologists, progressive family advocates. Widely	Focuses narrowly on child-rearing and alloparenting,

	neuroendocrine paternal substrate triggered by infant proximity.		respected across aisles.	leaving workplace dynamics and organizational design unaddressed.
Reeves (*Of Boys and Men*)	Modern institutions inadvertently disadvantage male developmental timelines.	Educational attainment data, labor statistics.	Centrist policymakers, educators. Highly influential for addressing male struggles without misogyny.	Proposes structural policy reforms (e.g., educational redshirting) but ignores intimate, interpersonal relationship dynamics.
Stock (*Material Girls*), **Joyce** (*Trans*), **Soh** (*The End of Gender*), **Murray** (*The War on the West*)	Biological sex is binary, immutable, and the necessary foundation for social structures and safeguarding.	Evolutionary biology, philosophy, political critique.	Gender-critical feminists, conservatives. Authors face severe backlash and protests.	Entirely consumed by the definitional war over *what* sex is. Offers zero guidance on how the sexes should integrate once defined.
Perel (*Mating in Captivity*), **Deida** (*Way of the Superior Man*), **Illich** (*Gender*)	Intimacy requires polarity; modern economic neutrality destroys relational passion and vernacular gender roles.	Psychoanalysis, Eastern mysticism, historical sociology.	Therapists, self-help seekers, philosophers. Highly polarized reception.	Divorced from empirical evolutionary biology and modern psychometrics. Operates as poetry, philosophy, or clinical observation.

The Evolutionary Architects and Ultimate Causes

This foundational category relies on evolutionary biology, sexual selection, and deep time to explain contemporary behavioural differences.

Matt Ridley's *The Red Queen* (1993) and David C. Geary's *Male, Female* (1998) provide the orthodox evolutionary psychology framework. Their central thesis is that sexual selection—specifically the profound asymmetry in obligatory parental investment, defined by female gamete size and gestation versus male gamete abundance—has driven the evolution of dimorphic mating strategies, risk profiles, and social architectures. Helen Fisher complements this by focusing on the neurochemistry of these evolved drives, examining how dopamine and oxytocin facilitate pair-bonding.

The evidence base for these texts relies heavily on cross-species primatology and foundational cross-cultural studies. A primary anchor for this literature is the highly replicated work of David Buss. Publishing in *Behavioral and Brain Sciences* (1989), Buss surveyed 10,047 individuals across 37 cultures and found robust, universally replicated sex differences in mate preferences. The data demonstrated that women globally place greater value on a mate's resource acquisition capabilities, while men prioritize cues to high reproductive capacity, such as youth and physical attractiveness[9]. The effect sizes for these preferences are enormous; the sex difference in age preferences reaches as high as $d = 2.00$, making it one of the largest psychological sex differences ever recorded[12].

The readership for these texts includes academics and the scientifically literate public. While establishing the paradigm, these authors have faced decades of intense criticism from developmental systems theorists and social constructivists who accuse them of genetic determinism and adaptationist storytelling. Ultimately, what these books fail to do is provide proximate, actionable frameworks. They offer ultimate explanations of *why* human nature evolved, but they lack a structural manual for how a modern dual-income couple or a highly matrixed corporate board should orchestrate their daily, interacting behaviours.

Group Dynamics and Societal Utility

Moving from mating to broader social structures, Joyce Benenson's *Warriors and Worriers* (2014) and Roy Baumeister's *Is There Anything Good About Men?* (2010) examine sex differences through the lens of group survival.

Benenson hypothesizes that men evolved for group cooperation optimized for out-group lethal conflict ("warriors"), which necessitated mechanisms for rapid conflict resolution and hierarchical integration. Conversely, women evolved to prioritize their own survival and the protection of highly vulnerable infants ("worriers"). As a result, women utilize exclusionary, covert, one-on-one relational tactics to eliminate resource competitors without risking direct physical injury[13]. Baumeister takes a macro-sociological approach, positing that men are the "disposable sex," operating at the extremes of the statistical distribution due to greater male variability. He argues that cultures flourish by exploiting male hyper-competitiveness, rewarding a tiny fraction of successful males with reproductive success while the majority are utilized for dangerous infrastructure and warfare.

The evidence base for these claims includes developmental psychology (observing children's play patterns) and historical mortality statistics. Furthermore, meta-analytic data supports the divergence in aggressive strategies. Archer (2000), publishing in *Psychological Bulletin*, conducted a meta-analysis of sex differences in intimate partner physical aggression. He found that women were slightly more likely to initiate one or more acts of physical aggression ($d = -0.05$), but men were significantly more likely to inflict serious physical injury ($d = 0.15$), reflecting the evolutionary divergence in physical capacity and the threshold for lethal violence[16].

While praised for identifying the mechanics of female relational aggression and male disposability, Benenson is heavily criticized by biologists for relying on contested theories of group selection, and Baumeister is largely ignored by mainstream sociology[13]. Crucially, both books remain purely descriptive. They illuminate *why* male and female group dynamics clash in modern institutions, but they do not propose a pragmatic mechanism for integrating these divergent cooperative strategies in a modern boardroom or household.

Constructivism, Dimorphism Denial, and the Blank Slate

This cohort vehemently opposes the evolutionary framework, arguing that sex differences in the brain and behaviour are either negligible, artifacts of pervasive socialization, or historically contingent. Steven Pinker's *The Blank Slate* (2002) is technically a critique of this category, dismantling the empiricist notion that the mind has no innate traits, but it serves to map the philosophical battlefield.

Lise Eliot's *Pink Brain, Blue Brain* (2009) and Gina Rippon's *The Gendered Brain* (2019) argue that "neurosexism" is rampant in science. They posit that there is no such thing as a "male brain" or "female brain," and that observed behavioural differences are the result of neuroplasticity responding to highly gendered socialization. Angela Saini's *The Patriarchs* (2023) extends this to sociology, arguing based on anthropological evidence of matrilineal societies that patriarchy is not a biological inevitability but a relatively recent historical construct tied to agriculture and property[19].

The primary evidence base for the neurological deniers includes a highly publicized meta-synthesis published in *Neuroscience & Biobehavioral Reviews* by Eliot et al. (2021). Analyzing structural MRI studies, Eliot concluded that sex accounts for less than 1% of the variance in human brain structure once corrected for total brain volume, urging the scientific community to "dump the dimorphism"[22].

These texts are widely celebrated in feminist academia. However, they face fierce methodological criticism from evolutionary neurobiologists. Critics, led by Marco Del Giudice, argue that Eliot and Rippon rely on univariate analyses that ignore how small regional neurological differences combine into highly dimorphic multivariate patterns[24]. Furthermore, critics argue they arbitrarily dismiss massive, replicated behavioural effect sizes, such as the male preference for working with things versus the female preference for working with people ($d = 1.0$ to 1.4), as mere socialization[25]. What these books fail to do is provide tools for living together. By insisting that all divergent behavioural profiles are illusory or oppressive

cultural artifacts, they offer no framework for couples or groups to manage the statistically real differences that *do* manifest, effectively advising men and women that their divergent subjective experiences are merely cultural mirages.

The Biosocial Synthesis and the Hormonal Battleground

Attempting to find the middle ground, this category examines how biology and environment co-create reality, with a heavy focus on endocrinology.

Robert Sapolsky's *Behave* (2017) argues that human behaviour cannot be understood through a single discipline; an action is the result of neurochemistry occurring seconds before, hormones acting days before, and genetics operating millennia before. Cordelia Fine's *Testosterone Rex* (2017) and Carole Hooven's *T: The Story of Testosterone* (2021) debate the specific role of hormones. Fine argues that the concept of testosterone as the master molecule of masculinity—inevitably driving aggression and risk—is a cultural myth used to justify inequality. Hooven counters that testosterone is indeed a profoundly powerful, biologically systemic hormone that fundamentally organizes and activates dimorphic physical and behavioural traits across the lifespan.

The evidence base here relies on peer-reviewed endocrinology. A defining study illustrating the biosocial synthesis is Eisenegger et al. (2010), published in *Nature*. In a double-blind, placebo-controlled study utilizing the ultimatum game ($N = 40$ women, later replicated in men), the researchers found that subjects who *believed* they received testosterone behaved much more unfairly, demonstrating the power of cultural stereotypes[27]. However, those who *actually* received exogenous testosterone made significantly *fairer* offers[27]. The critical mechanism identified is that testosterone does not drive blind aggression, but rather *prosocial status-seeking*; in an ultimatum game, fairness secures status and prevents the humiliating rejection of an offer[28]. Correspondingly, a massive meta-analysis by Geniole et al. (2020) found only a very small positive correlation ($r = 0.054$) between baseline testosterone and human aggression, supporting the status-seeking hypothesis over the aggression hypothesis[31].

While Sapolsky is universally acclaimed for his rigorous synthesis, Fine and Hooven remain championed by opposing ideological camps. Ultimately, this literature remains trapped at the molecular and neurochemical level. Neither book scales the neuroendocrine data up into a holistic, pragmatic sociological model for family or corporate structures.

Cooperative Breeding and the Paternal Brain

Sarah Blaffer Hrdy's *Mothers and Others* (2009) and *Father Time* (2024) fundamentally disrupt both orthodox evolutionary psychology and social constructivism. Hrdy posits that humans are "cooperative breeders." In *Father Time*, she explicitly challenges the assumption that only women possess a biological nurturing instinct, arguing that men possess a latent "alloparental substrate" that, when triggered by proximity to an infant, fundamentally rewires the male brain.

The evidence base for this is highly robust. Primary neuroendocrinology demonstrates that active, proximate fatherhood causes a drop in baseline testosterone and significant spikes in oxytocin, prolactin, and vasopressin[33]. Furthermore, the sociological outcomes of this biological rewiring are profound. A systematic meta-analysis by Sarkadi et al. (2008) in *Acta Paediatrica*,

reviewing 24 studies comprising approximately 22,000 data points, showed that active father involvement drastically reduces externalizing behavioural problems in boys, reduces psychological problems in young women, and enhances cognitive development globally[35]. The findings on father involvement are heavily replicated and control for socioeconomic status. Hrdy's work is widely respected across disciplines for integrating rigorous evolutionary biology with progressive social applications. However, her focus remains narrowly on child-rearing and alloparenting. The books leave workplace dynamics, romantic couplehood, and broader organizational design largely unaddressed.

The Gender-Equality Paradox and Modern Policy

This category addresses the macro-level societal shifts occurring in late-stage, post-industrial democracies, most notably Richard Reeves's *Of Boys and Men* (2022). Reeves argues that modern educational and economic institutions, having rightly dismantled structural barriers for women, have inadvertently created environments that are deeply hostile to male developmental timelines and behavioural baselines. While highly influential in centrist policy circles for addressing male struggles without resorting to reactionary misogyny, it is a structural policy book (recommending interventions like the educational redshirting of boys) rather than a guide for interpersonal dynamics.

However, the deepest theoretical debate in this macro-societal realm belongs to the academic literature surrounding the "Gender-Equality Paradox." A highly replicated, deeply counterintuitive finding in modern sociology is that as societies become *more* egalitarian and wealthy, psychological and occupational sex differences *increase* rather than decrease. Schmitt et al. (2008), publishing in the *Journal of Personality and Social Psychology*, demonstrated this in a study of 17,637 individuals across 55 nations, finding that sex differences in Big Five personality traits maximize in highly developed, egalitarian nations[36]. Falk & Hermle (2018), in *Science*, found the exact same pattern for altruism, trust, and risk-taking across 80,000 individuals in 76 countries[26]. Most controversially, Stoet & Geary (2018) in *Psychological Science* analysed data from 472,242 adolescents globally. They found that while girls are highly capable in STEM subjects universally, in wealthy, egalitarian countries, women rely on their *relative* intra-individual advantage in reading and verbal skills to choose non-STEM careers, whereas women in poorer countries choose STEM for absolute financial security[26].

This data represents the most intense controversy in the field. Social constructivists and critics like the GenderSci Lab (Richardson et al., 2020) and Ilmarinen & Lönnqvist (2024) argue the paradox is a methodological artifact, criticizing the use of difference scores and unvalidated propensity metrics[40]. Conversely, evolutionary psychologists maintain it is evidence of the "resource hypothesis": when cultural and economic constraints are removed, innate biological predispositions and sexually dimorphic preferences are finally free to manifest[38]. None of the current trade books successfully translate this paradox into actionable advice for organizations navigating diversity targets.

The Gender Identity Wars

Kathleen Stock (*Material Girls*), Helen Joyce (*Trans*), Debra Soh (*The End of Gender*), and Douglas Murray (*The War on the West*) represent a cluster of books arguing that biological sex is binary, immutable, and the necessary foundation for women's rights, medical safeguarding,

and Western institutional stability. They argue that the concept of subjective "gender identity" is scientifically incoherent and socially destructive.

Their evidence base relies on evolutionary biology, gametic definitions of sex, detransition data, and philosophical logic[43]. Authors like Stock and Soh have faced immense cultural backlash, campus protests, and accusations of transphobia from activists and progressive academics[45].

What these books absolutely fail to do is provide a roadmap for the future. They are fundamentally defensive and polemical, entirely consumed by the definitional war over *what* a man or a woman is. Consequently, they offer zero guidance on how men and women, once defined, should romantically, domestically, or professionally integrate.

Relational Dynamics and Esoterica

The final category includes Esther Perel's *Mating in Captivity* (2006), David Deida's *The Way of the Superior Man* (1997), and Ivan Illich's *Gender* (1982).

Perel relies on clinical psychology to argue that modern couples demand their partner be both their egalitarian best friend (requiring safety) and their erotic lover (requiring mystery and power dynamics), which are contradictory drives[48]. Deida uses Eastern mysticism to argue that intimacy requires sexual polarity, and that neutralizing "masculine" and "feminine" essences destroys passion[50]. Illich uses historical sociology to draw a sharp distinction between "vernacular gender" (the historically rooted, asymmetrical division of labor) and "economic sex" (modern capitalism treating humans as neutered economic units)[51].

While highly popular (Perel) or maintaining cult status (Deida, Illich), these books are entirely divorced from empirical evolutionary biology and modern psychometrics. They operate as poetry, philosophy, or clinical observation, lacking the rigorous statistical foundation required to build robust institutional models.

The Unoccupied Position: The Gap

The exhaustive survey of the literature reveals a glaring, unoccupied space. The existing books fail to provide a cohesive, empirically grounded, and practical framework for modern living because they are trapped in several enduring false dichotomies:

1. **The Polemical Trap:** Authors are either defending the blank slate against biology (Eliot, Fine, Saini) or defending biological reality against the blank slate (Soh, Stock, Pinker). The books function as weapons in a culture war, rather than tools for living.
2. **The Level-of-Analysis Trap:** The evolutionary biologists (Buss, Geary) flawlessly explain our Pleistocene origins but fail to translate this into modern organizational behavior. The clinical and spiritual writers (Perel, Deida) identify the symptoms of modern relational malaise but lack empirical grounding.
3. **The Statistical Trap:** The literature routinely fails to distinguish between the univariate average and the multivariate individual.

The gap this new book must fill is: A pragmatic, non-polemical synthesis that operationalizes the *reality of statistical sex differences* for the explicit purpose of designing highly cooperative, functional structures (dyads, families, teams, and societies).

This book must assume that physiological dimorphism and overlapping behavioural distributions are settled science. It must bypass the sterile "nature vs. nurture" debate by fully

adopting the tripartite biosocial framework: biology provides the baseline, behaviour is the statistical manifestation, and culture acts as the multiplier. Finally, it must answer the practical question: *Given that men and women possess bimodal physiology and overlapping but distinctly different multivariate psychological profiles, how do we design environments where both can thrive without enforcing 1950s gender roles or pretending everyone is an interchangeable economic unit?*

Summary of Robust Findings

The empirical literature yields several highly robust, replicated findings that must form the foundation of any practical application. First, while univariate psychological sex differences are generally small on average ($d = 0.21$), multivariate analyses demonstrate that combined psychological profiles are deeply sexually dimorphic, with global overlap as low as 10% ($D = 2.71$). Second, human mating preferences remain highly differentiated across cultures, with males prioritizing cues to fertility and females prioritizing resource acquisition ($d = 2.00$). Third, the "Gender-Equality Paradox" robustly demonstrates that in wealthy, egalitarian nations, sex differences in personality and occupational choices maximize rather than minimize. Fourth, testosterone primarily drives prosocial status-seeking behaviour rather than indiscriminate aggression, aligning with environmental incentives. Fifth, human males possess a latent, neuroendocrinologically conserved capacity for active "alloparenting" that, when triggered, drastically improves child developmental outcomes. Finally, institutional dynamics are heavily modulated by environmental sex ratios, which dictate the frequency and nature of workplace interactions and harassment.

Contested or Open Questions

Question / Domain	Nature of the Controversy	Leading Theorists / Critics
The Gender-Equality Paradox	Do sex differences maximize in egalitarian nations due to the freedom to express innate biological predispositions, or is the paradox an artifact of shifting cultural stereotypes and unvalidated statistical difference scores?	Stoet & Geary, Falk & Hermle (Proponents) vs. GenderSci Lab, Ilmarinen & Lönnqvist (Critics).
Brain Dimorphism	Does the human brain exhibit true multivariate sexual dimorphism, or is it an overlapping "mosaic"	Lise Eliot, Gina Rippon (Mosaic/Volume) vs. Marco Del Giudice (Multivariate Dimorphism).

	where sex accounts for a negligible percentage of variance once corrected for gross volume?	
Intimate Partner Violence	To what extent is IPV strictly bidirectional and symmetrical in normative populations versus heavily male-skewed in clinical/criminal populations?	John Archer (Symmetry in initiation) vs. Feminist Sociologists (Asymmetry in severity/control).
Hormonal Exogeneity	How do hormonal contraceptives and ubiquitous endocrine-disrupting chemicals fundamentally alter human mate selection and relational stability at the population level?	Evolutionary Psychologists vs. Pharmacological Researchers (Ongoing open empirical question).

Implications for Living Together

In translating empirical science into practical application, the analysis must strictly avoid the naturalistic fallacy—the assumption that what is biologically "natural" is morally "good" or socially optimal. Biology provides a set of descriptive parameters and statistical baselines; it does not dictate moral imperatives. For couples, families, organisations, and societies to thrive, institutions must abandon the premise that fairness requires identical behaviour or identical outcomes. The statistical reality of overlapping univariate distributions combined with highly dimorphic multivariate profiles demands that institutions be designed to account for biological *averages* while remaining radically flexible to accommodate *individuals*.

For couples and families, the robust evidence of male neuroendocrine plasticity regarding fatherhood fundamentally destroys the assumption that mothers are the sole biologically provisioned caregivers. Policies and domestic arrangements must aggressively incentivize active fatherhood, which not only benefits infant cognitive development but stabilizes adult male psychology. Furthermore, observational data by researchers such as Gottman demonstrates that stable couples require a 5:1 ratio of positive to negative interactions[53]. Acknowledging the biological reality of differing mate retention strategies and conflict resolution styles allows couples to achieve this ratio by building bespoke conflict-management protocols, rather than pathologizing the other's biological baseline.

For organisations and societies, the "Gender-Equality Paradox" implies that pushing for strict 50/50 gender parity in all professions—such as engineering or early childhood education—may be fighting against deeply ingrained, freely chosen preferences rather than dismantling systemic oppression. Organisations should focus entirely on equality of opportunity and the eradication of workplace harassment. This requires paying close attention to environmental sex-ratio dynamics, as minority sexes in highly skewed occupations face vastly different integration challenges and harassment risks[55]. If society accepts that men and women

generally possess overlapping but distinctly different multivariate profiles, it functions best when it leverages this complementary cognitive and behavioural diversity. We must treat statistical sex differences not as a pathological problem to be solved by social engineering, but as a robust evolutionary asset to be harnessed for collective flourishing.
